# Guarding the commons: how community managed software projects protect their work<sup>☆</sup>

Siobhán O'Mahony\*

## Abstract

Theorists often speculate why open source and free software project contributors give their work away. Although contributors make their work publicly available, they do not forfeit their rights to it. Community managed software projects protect their work by using several legal and normative tactics, which should not be conflated with a disregard for or neglect of intellectual property rights. These tactics allow a project's intellectual property to be publicly and freely available and yet, governable. Exploration of this seemingly contradictory state may provide new insight into governance models for the management of digital intellectual property.

## 1. Introduction

It's a kind of cool to bring the power to where it belongs and what's really exciting about working with the hackers is that .... if you're [a] hacker and you leave [a firm] and you've done this work for hire, then you no longer own your product. Well, with open source, you own your stuff right? (*Contributor, GNOME a Graphical User Interface (GUI) Desktop Project.*)

Open source software shares some similarities with privately produced pure public goods, but also differs

from traditional definitions of public goods in important ways. It is owned and governed by a bounded community of individuals as opposed to a government, consortium or single private actor. While open source and free software is publicly available and redistributable, contributors to community managed software projects do maintain and exercise rights over their work.<sup>1</sup> A community managed software project is an open source or free software project initiated and managed by a distributed group of people who do not share a common employer. Project contributors may consider themselves to be associated with either the free software or open source social movements or unaffiliated with a social movement. Contributors may be sponsored by firms, but they are not employees

<sup>1</sup> In suggesting that open source software may differ from pure public goods in important ways, the intent is not to question the degree to which the public benefits from the provision of open source software, but to reconcile assumptions about open source software with empirical findings from the field.

45 of the project and project relations are not guided by  
46 employment relations.<sup>2</sup>

47 Observers of the open source phenomena question-  
48 ing why contributors to community managed projects  
49 would give their work away for free have neglected  
50 to examine what is given away (code) and what is re-  
51 tained (rights). The property rights programmers exer-  
52 cise to sustain their collective goods are thus not fully  
53 appreciated. Empirical examination of how six com-  
54 munity managed projects manage their work indicates  
55 that they use the legal techniques of copyright, trade-  
56 mark, software licensing, and incorporation to protect  
57 their collective works. However, the types of threats  
58 that they defend against differ from the threats typi-  
59 cally targeted with these legal techniques.

60 First, I explicate attributes that open source soft-  
61 ware shares with public good and common pool re-  
62 source models. Next, I discuss the research methods  
63 and mechanisms used to protect six community man-  
64 aged software projects. Analysis of these mechanisms  
65 motivates a discussion of the practices used to man-  
66 age common pool resources. A conceptualization of  
67 open source software that more explicitly recognizes  
68 its collective governance is advanced. I conclude by  
69 exploring ways in which this conception might chal-  
70 lenge existing assumptions about the nature of com-  
71 munity managed software and inform future research.

## 72 2. Public goods and common pool resources

73 Open source software is often characterized as a  
74 privately produced public good (Kollack, 1998, 1999;  
75 Lerner and Tirole, 2002a; Johnson, 2001; Bessen,  
76 2001; Weber, 2000; Hars and Ou, 2000). First, it is  
77 the product of private-collective efforts. Volunteer  
78 contributors, sponsored contributors, firms, govern-  
79 ments, and non-profits all may contribute hardware,  
80 software, or their expertise to community managed  
81 projects. Second, it can be considered a public good  
82 because it is non-exclusive and joint in supply. A  
83 good that is non-exclusive is available to one if it

<sup>2</sup> I use the term community managed software project to distinguish from open source and free software projects that can be sponsored and managed by firms, for firms can also start and manage open source projects. The terms 'open source' and 'free software' are used to refer to the type of license terms associated with particular software.

84 is available to all. A good that is joint in supply is  
85 indivisible: its availability to others does not diminish  
86 when consumed by one individual (Snidal, 1979).

87 Open source software meets the definition of a  
88 non-exclusive good, as it is publicly and freely avail-  
89 able (although it can also be purchased for a fee  
90 by those desiring the convenience of a commercial  
91 format).<sup>3</sup> It can be downloaded from the Internet and  
92 used freely even by those who did not contribute to  
93 its development. Contributors to open source projects  
94 do not wish to exclude others.<sup>4</sup> Open source software  
95 could also be considered joint in supply as increased  
96 use of it does not diminish its value or supply. Olson  
97 argued that when the benefits from collective contri-  
98 butions are non-exclusive, rational actors would have  
99 inadequate incentives to contribute to such ventures  
100 and thus be more likely to under-invest in public  
101 goods (Olson, 1965). Yet, in the case of open source  
102 software, thousands of volunteers<sup>5</sup> donate their pri-  
103 vate resources to produce open source software with  
104 the knowledge, and even hope, that non-contributors  
105 will also benefit from their efforts.

106 Scholars have addressed this puzzle by identifying  
107 benefits that might be exclusive to private contribu-  
108 tors but not to potential free riders. Thus, Von Hippel  
109 and von Krogh consider the open source development  
110 model to be a 'private-collective' model of innovation:  
111 privately funded with collective benefit (2002, p. 18).  
112 They argue that programmers contribute freely to the  
113 provision of a public good because they garner pri-  
114 vate benefits from doing so. For example free riders  
115 do not get the private learning benefits that contribu-  
116 tors accrue from developing software for open source  
117 projects. Nor do they get code developed to satisfy pre-  
118 cisely the needs of free riders—contributors develop  
119 code to satisfy their own needs (Raymond, 1999).

<sup>3</sup> Firms selling products and services that use open source and free software contribute value by packaging it with other software, installing it on hardware and/or providing service and support contracts.

<sup>4</sup> The very definition of open source prohibits discrimination against persons, groups or fields of endeavor (Open Source Initiative, 2001).

<sup>5</sup> As of this writing, more than 500,000 software users and/or contributors are registered on <http://www.sourceforge.net>, and 12,000 users are registered on <http://www.savannah.gnu.org>, the two largest hosts to free software and open source projects. While some contributors to open source projects may be sponsored by firms, they are still volunteers to community projects.

120 Lerner and Tirole (2002a) also examined benefits  
121 that might be exclusive to contributors of community  
122 managed projects. They reasoned that project contrib-  
123 utors who signal their talents to the market via their  
124 contributions could increase their reputations and gain  
125 private marketplace rewards as a result. The career  
126 benefits that can be obtained in this way might ex-  
127 ceed the benefits that could be obtained by retaining  
128 it under proprietary control. This argument was found  
129 to be partly correct in a study by Hann et al. (2002).  
130 While not all open source volunteer contributors experi-  
131 enced a reported increase in their work wages, those  
132 with a higher ranking within a particular open source  
133 project did indeed experience higher wages in their  
134 regular full time jobs. (However, if those in leadership  
135 positions also have greater skill and experience, this  
136 effect could be confounded by salary increases earned  
137 independent of leadership positions on open source  
138 projects.)

139 Additional empirical work elaborates upon the na-  
140 ture of private benefit obtained by contributors to open  
141 source projects. Lee and Cole (2000), Hars and Ou  
142 (2000), Lakhani et al. (2002) have all found that pro-  
143 grammers contribute to open source software for both  
144 internal (altruism, fun, reciprocity) and external (im-  
145 proving job and career prospects) reasons. Lakhani  
146 et al. (2002) found that the intrinsic value of partic-  
147 ipating, contributing, and learning from highly  
148 skilled peers in a technical community is important  
149 in explaining the attraction of many contributors to  
150 open source projects. Butler et al. (in press) study of  
151 the management and maintenance of on-line groups  
152 also showed that social benefits were important to  
153 explaining why people contribute to on-line com-  
154 munities. They found that expected benefits from  
155 participating in on-line groups predicted the involve-  
156 ment of contributors and, in particular, community list  
157 managers.

158 While this research explains why people might  
159 contribute to a privately produced public good, how a  
160 'private-collective' innovation model (Von Hippel and  
161 von Krogh, 2003) sustains itself remains unclear. As  
162 Lerner and Tirole (2002b) point out, the terms "open  
163 source" and "free software" refer to the licensing terms  
164 associated with a piece of software. Licenses may  
165 guide the terms of use, but the possibility of hijacking a  
166 community managed project always exists (Lerner and  
167 Tirole, 2002b). A project is hijacked when a commer-

168 cial vendor adds proprietary code to the community's  
169 work and attempts to privatize it (Lerner and Tirole,  
170 2002b). If this is true, what prevents such out-  
171 comes from happening? How are the commons  
172 protected?

173 If a commercial vendor hijacked a community man-  
174 aged project, the future stream of benefits that would  
175 stem from the collective resource would be made  
176 unavailable to the community. This type of problem  
177 shares some features with non-renewable resources  
178 or common pool resource problems. Hardin's (1968)  
179 "Tragedy of the Commons" theorized that, if all in-  
180 dividuals maximized their gains when drawing from  
181 non-renewable resources, these resources would, over  
182 time, diminish. Because the individual cost of using  
183 the resource would always be less than the collective  
184 cost, individuals would have no incentive to show  
185 temperance (Hardin, 1968). People following their  
186 own short-term interests would produce outcomes  
187 that were not in anyone's long-term interests (Ostrom  
188 et al., 1999). Ostrom and her colleagues (Ostrom,  
189 1990, 1999; Ostrom et al., 1994, 1999) have theoret-  
190 ically and empirically challenged Hardin's assump-  
191 tions as well as his dismal conclusions (1968). They  
192 argue that his metaphor mischaracterizes the problem  
193 of common pool resources.

194 The tragedy of the commons only becomes a  
195 tragedy if the actors using the commons are "norm-  
196 free maximizers of immediate gains, who will not  
197 cooperate to overcome the common dilemmas they  
198 face" (Ostrom, 1999, p. 493). The common resource  
199 pool perspective recognizes human actors as capable  
200 of cooperating with each other and of establishing  
201 norms and social mechanisms to encourage and rein-  
202 force cooperative behavior.

203 Recent reviews of field and experimental studies  
204 (Ostrom, 1999; Ostrom et al., 1999; Sneath, 1998;  
205 Schlager, 1994) indicate that groups can learn to solve  
206 problem and develop solutions to manage common  
207 goods in sustainable ways. In some cases, locally  
208 designed mechanisms to manage natural resources  
209 outperformed more centralized solutions (Schlager,  
210 1994). Thus, and thankfully so, the tragedy of the  
211 commons may be overstated.

212 Ostrom and colleagues (Ostrom, 1990, 1999;  
213 Ostrom et al., 1994, 1999) have identified two pri-  
214 mary characteristics of such dilemmas: the difficulty  
215 of exclusion and subtractability. Like public goods,

216 common pool resources are either non-exclusive or  
 217 the costs of excluding others is effectively prohibitive.  
 218 Common pool resources are also subtractable, which  
 219 is the opposite of joint in supply. Goods that are  
 220 subtractable are reduced in value with continued use.  
 221 Exploitation by one reduces the availability of the  
 222 resource for others (Ostrom et al., 1999).

223 To return to the comparison between public and pri-  
 224 vate goods, we have established that open source and  
 225 free software is privately produced and non-exclusive.  
 226 This meets the definition of both public goods and  
 227 common pool resources. The next dimension is more  
 228 ambiguous: Is open source and free software sub-  
 229 tractable or joint in supply? If one person downloads  
 230 software for his or her personal use, the amount avail-  
 231 able for the next person is unchanged. However, it  
 232 requires more protections than those offered by the  
 233 public domain. To remain open and publicly available,  
 234 it must be protected from proprietary appropriation.  
 235 Thus, open source and free software appear to be joint  
 236 in supply, but is in fact vulnerable to usage that would  
 237 threaten its availability to all. Use of it will not di-  
 238 minish in the present, but the future stream of benefits  
 239 is at risk.<sup>6</sup> Thus, it is not subtractable in the manner  
 240 previously defined, but it does share some features of  
 241 a common pool resource problem in that the regula-  
 242 tion of behavior in a manner that maximizes collective  
 243 gain is of concern. This research empirically examines  
 244 how community managed projects protect and sustain  
 245 their work.

### 246 3. Methods

247 This research was guided by an inductive, qualita-  
 248 tive approach using ethnographic methods. A qualita-  
 249 tive approach can help explain how theoretical prin-  
 250 ciples are enacted in particular cases (Van Maanen,  
 251 1998), in particular, those cases that defy existing cat-  
 252 egories or theoretical explanations. Furthermore, qual-  
 253 itative methods are most suitable for grounded theory  
 254 building (Eisenhardt, 1989). Grounded theory build-  
 255 ing has three distinct features: theoretical sampling,  
 256 the making of constant comparisons, and the use of  
 257 a coding paradigm to ensure conceptual development

(Strauss, 1987). All three tactics were used in this  
 258 research. 259

260 First, multiple sources of information enabled tri-  
 261 angulation and validation of theoretical constructs  
 262 that could withstand analysis from varying perspec-  
 263 tives. Data was collected from three primary sources:  
 264 (1) observation at project and user group meetings,  
 265 technical presentations and conferences; (2) infor-  
 266 mant interviews; and (3) project data archived on  
 267 the Internet that detailed project interactions and  
 268 structural developments. Over 90 h were spent ob-  
 269 serving and meeting informants at 27 different events  
 270 (project meetings, user group meetings and confer-  
 271 ences) between April 2000 and 2001. Seventy-five  
 272 semi-structured interviews were conducted with con-  
 273 tributors to open source projects. A summary of  
 274 informant information is provided in Table 1. Most  
 275 (84%) were conducted in person, although some  
 276 (16%) were conducted over the phone. Gaining an  
 277 understanding of membership, sponsorship, decision-  
 278 making, governance and ownership practices used on  
 279 open source projects was an important focus of the  
 280 interviews.

281 Fifty-six percent of informants were identified  
 282 through face-to-face means while others were identi-  
 283 fied directly through on-line documentation of their  
 284 project or from referrals from other informants. About  
 285 two-thirds of the respondents could be identified as  
 286 having a corporate sponsor that allowed them to work  
 287 on community managed projects as part of their em-

Table 1

*N* = 75.

<sup>a</sup> Volunteer contributor who contributes to open source projects in his or her own free time.

<sup>b</sup> Individual who contributes to open source projects as part of his or her employment.

<sup>6</sup> I thank von Hippel for helping to clarify this point.

288 ployment. The selection of informants was guided by  
 289 maximizing the variance in perspective of as many  
 290 different types of actors as possible. Obtaining the  
 291 perspective of volunteers, volunteers sponsored by  
 292 firms and firm and non-profit representatives helped  
 293 to explicate how different motivations, interests and  
 294 roles affected community practices.

295 Second, after an initial set of interviews, theoret-  
 296 ical sampling guided the selection of six projects to  
 297 examine at a greater level of detail, projects that were  
 298 large, technically mature, attracted commercial atten-  
 299 tion, and that varied in their relations with firms. More  
 300 information about the characteristics of each project  
 301 is provided in Table 2. Project data was collected  
 302 from on-line archives and included documents such  
 303 as: mission statements, charters, bylaws, meeting min-  
 304 utes, and mailing list archives. Interviews were tran-  
 305 scribed and then coded and analyzed along with other  
 306 sources of qualitative data using Atlas TI software, a  
 307 qualitative coding application. Over 54,000 lines of  
 308 text were coded to identify the practices community  
 309 managed projects used to manage and protect their  
 310 work. The variance inherent in different types of actors  
 311 and their different roles facilitated the process of con-  
 312 stant comparison and the development of codes and  
 313 constructs.

#### 314 4. Findings: tactics to prevent 315 proprietary appropriation

316 How do community managed software projects pro-  
 317 tect against the threat of proprietary appropriation? I  
 318 identified seven primary tactics: (1) adopt software li-  
 319 censes with distribution terms that restrict proprietary  
 320 appropriation; (2) encourage compliance with licens-  
 321 ing terms through normative and legal sanctions; (3)  
 322 incorporate to hold assets and protect individual con-  
 323 tributors from liability; (4) transfer individual property  
 324 rights to collectively managed non-profit corporations;  
 325 (5) trademark the brands and logos designed to repre-  
 326 sent their work; (6) assign trademarks to a foundation;  
 327 and (7) actively protect the project's brand. Table 3  
 328 shows which tactics are used by the six projects and  
 329 the types of data used to support these findings. After  
 330 discussing how each of these tactics are used, I exam-  
 331 ine how to integrate two seemingly irreconcilable con-  
 332 cepts: a good that is freely and publicly available, and

yet collectively managed and protected. With a more 333  
 nuanced understanding of the nature of open source 334  
 software, comparisons with public goods and common 335  
 pool resources are re-evaluated. 336

#### 4.1. Licensing terms that restrict 337 proprietary appropriation 338

The distribution terms associated with many open 339  
 source and free software licenses are designed to guard 340  
 against some of the free rider problems associated 341  
 with the private provision of public goods. Many open 342  
 source licenses stem from variations of the first free 343  
 software license, the GNU<sup>7</sup> General Public License 344  
 (hereafter GPL). This license was developed when, 345  
 frustrated by the use of proprietary restrictions asso- 346  
 ciated with Unix, Richard Stallman<sup>8</sup> decided to build 347  
 a free operating system, the GNU system in 1984. 348  
 However, Stallman realized that if his free software 349  
 was in the public domain, it might not remain freely 350  
 available. 351

But then I thought about the question of whether 352  
 people would change the software and make pro- 353  
 prietary versions of it. And I realized that if they 354  
 did that, they could defeat the whole point, they 355  
 could negate the effort. Someone could make an 356  
 improved proprietary version and it could displace 357  
 the free version. And as a result, people might be 358  
 using my code but they would not have the free- 359  
 dom that I hoped they would have and I would not 360  
 have it either, unless I kept using the inferior free 361  
 version. *But if nobody joined me, it would not do* 362  
*much good.* And so I decided to look for some way 363  
 I could stop that from happening. And in discus- 364  
 sions with a lawyer I worked out the idea of copyleft 365  
 (*Interview with Richard Stallman, 20 March 2001,* 366  
*emphasis added*).<sup>9</sup> 367

Stallman realized that if he put his code in the 368  
 public domain, it could be appropriated and made 369

<sup>7</sup> GNU is based on the recursive acronym "GNU is Not Unix" (Stallman, 1999).

<sup>8</sup> Stallman went on to found the Free Software Foundation, the organization that remains primarily responsible for interpreting and defending the license.

<sup>9</sup> The names of all informants have been disguised to preserve anonymity except in cases where informants permitted their names to be used.

Table 2  
Project attributes

Project names/project attributes	GNU project	Linux kernel	Apache webserver	Debian Linux distribution	GNOME GUI desktop	Linux standards base
Founding mission/goal	To develop a free Unix-like operating system	To rewrite MINIX	To create a commercial grade freely available webserver	To develop a free non-commercial operating system	To build a free and easy to use desktop environment	To develop & promote standards to increase compatibility among Linux distributions
Date project founded	January 1984	Summer 1991	February 1995	August 1993	August 1997	June 1995
Date of first release	Spring 1985	1992	April 1995	January 1994	June 1998	May 1998
Primary license used	GPL	GPL	Apache (BSD type)	GPL	GPL	GPL
Foundation formed	Yes	No	Yes	Yes	Yes	Yes
Type of corporation	Public benefit	–	Public benefit	Public benefit	Public benefit	Mutual benefit
Date incorporated	October 1985	–	June 1999	June 1997	August 2000	May 2000
Non-profit status	501(c)(3)	–	501c(3)	501c(3)	501c(3)	501c(6)
Date awarded	~1987	–	April 2001	June 1999	Pending	2001
Membership association	No	–	Yes	Yes	Yes	Yes
Companies as members	No	–	No	No	No	Yes
Board officers	Appointed	–	Elected	Appointed	Elected	Elected

Table 3  
Tactics to prevent proprietary appropriation

S. no.	Tactic	In practice	Projects						
			GNU project	Linux kernel	Apache webserver	Debian Linux	GNOME GUI desktop	Linux standards base	Frequency of use
1	Restrict proprietary usage	“GNOME was GPL'd to enforce, to protect software that gets developed from [getting] proprietary features. The license has to be used strategically.” ( <i>Project Founder, GNOME</i> )	I, D, S	I, D, S	–	I, D	I, D	I, D, S	5/6
2	Legal/normative sanctions	“If the GPL is violated for FSF copyrighted software, then it is up to us to enforce it.” ( <i>Founder, GNU Project</i> )	I, D, S	I, D, S	I	I, D, S	I	I, D, S	6/6
3	Incorporate	“Somewhere along the line, someone might want to sue somebody. We want to make sure that Debian has an umbrella over it, so that people who are working on this potentially as a hobby are not exposing themselves to risk.” ( <i>Founder, Debian Project</i> )	I, D, S	–	I, D, S	I, D, S	I, D, S	I, D, S	5/6
4	Foundation holds copyrights	“So we took the stance that you should have an organization that owns the code, so the Apache Software Foundation does own the copyright on all the code.” ( <i>Founding Member, Apache</i> )	I, D	–	I, D	I, D <sup>a</sup>	–	I, D	4/6
5	Create logo and file trademark	“When the Linux trademark was under attack in 1997, we garnered the funds to hire an attorney to wrest it away from the guy who was trying to use it as a weapon.” ( <i>Executive Director, Linux International</i> )	I, D, S	I, D, S	I, D, S	I, D, S	I, D, S	I, D, S	6/6
6	Foundation holds trademarks	“The [foundation] shall have the right to inspect any products and any and all materials . . . . Which use the Trademarks to assess the level of consistency and quality of such use.” ( <i>Trademark License Agreement, July 2002, Linux Standards Base</i> )	I	–	I, D	I, D	I, D	I, D	5/6

<sup>a</sup> Debian's Foundation does not encourage contributors to reassign their copyrights to the foundation, but the foundation does hold some copyrights.

370 proprietary. He also recognized, as the quote indicates,  
371 that if he did not protect free software from appropri-  
372 ation, others would be reluctant to share their code as  
373 well.

374 The GPL is a copyright license designed with  
375 unique distribution terms, using principles Stallman  
376 termed “copyleft.” “Copyleft uses copyright law, but  
377 flips it over to serve the opposite of its usual purpose:  
378 instead of a means of privatizing software, it becomes  
379 a means of keeping software free” (Stallman, 1999,  
380 p. 59). The GPL permits users to access the source  
381 code, modify it and redistribute software (Stallman,  
382 1999; Moglen, 1999). However, Section (2)(b) of  
383 the license requires that all modifications or derived  
384 works released to the public must also be redistributed  
385 under the same terms.

386 You must cause any work that you distribute or pub-  
387 lish, that in whole or in part contains or is derived  
388 from the Program or any part thereof, to be licensed  
389 as a whole at no charge to all to third parties under  
390 the terms of this License (*Free Software Founda-*  
391 *tion, Section (2)(b), GNU General Public License,*  
392 *Version 2, June 1991).*

393 This license uses copyright law to achieve a goal that  
394 differs from the ends to which copyright law is tradi-  
395 tionally applied (Stallman, 2001). The goal of copy-  
396 right is to restrict unauthorized use, copying, distribut-  
397 ing, modifying, and performing.<sup>10</sup> The goal of copy-  
398 left is to allow these same activities, but to restrict  
399 proprietary appropriation. Unlike software in the pub-  
400 lic domain, works derived from software licensed un-  
401 der the GPL cannot be made proprietary. With this  
402 self-perpetuating clause, the GPL not only establishes  
403 a commons (Moglen, 1999), but a fence that protects  
404 that commons.

<sup>10</sup> Authors of original works are allowed copyright protection under Title 17 of the United States Code. Section 106 of the 1976 Copyright Act grants owners of copyrights, the rights to authorize others to reproduce works, prepare derivative works, distribute and to perform or display the work publicly. The 1980 Amendments to the 1976 Act extended this law to apply to computer programs (defined as “a set of statements or instructions to be used directly or indirectly in a computer in order to bring about a certain result”). (17 USC 106 and “Copyright Basics” located at <http://www.loc.gov/copyright/circs/circ1.html>).

405 More specialized licenses,<sup>11</sup> have emerged since the  
406 word open source was coined in 1998,<sup>12</sup> but the ma-  
407 jority of community managed projects use the GPL.  
408 Five of the six community managed projects examined  
409 as a part of this study licensed their work under the  
410 GPL.<sup>13</sup> Project members reported that they adopted  
411 the GPL, explicitly with the protections offered by  
412 Section (2)(b) in mind:

413 The GPL is a sort of the standard license that people  
414 were using at the time. So it was just naturally used.  
415 For the most part when you see a project appear  
416 in the community it tends to be GPL'd (*Sponsored  
417 Contributor, GUI Desktop Project*).

418 This informant confirms what Lerner and Tirole  
419 (2002b) found: of 25,792 projects that they studied  
420 from <http://www.sourceforge.net>, 70% of them used  
421 the GPL. All contributors to community managed  
422 projects that used the GPL reported being very aware  
423 of its terms and conditions. One might question how-  
424 ever how understanding and compliance could be  
425 garnered from users who do not necessarily purchase  
426 the software.

427 Without a transaction,<sup>14</sup> agreement with the GPL  
428 is established by making the freedoms to use, copy  
429 and modify the software contingent upon agreement  
430 with the restrictions associated with it. For example  
431 the terms of the license hold that modifying or dis-  
432 tributing a GPL program, indicates acceptance of the  
433 license (*Free Software Foundation, 1991*). In effect,

<sup>11</sup> As of this writing, there are 30 open source licenses that meet the definition of open source (<http://www.opensource.org/licenses/index.html>). Many, but not all, of these licenses also meet the definition of free software. For the purposes of this paper, only one license is discussed, the GNU GPL. The more recently approved open source licenses are often based on the GNU GPL, but typically have several modifications most often with regard to restrictions on the licensing and use of derivative works.

<sup>12</sup> The word open source was created in 1998 to create a marketing term for free software that was more hospitable to commercial interests (Raymond, 1999).

<sup>13</sup> One project, that does not use the GNU GPL, the Apache webserver project, uses a different license (the Apache license) that is based on the Berkeley Software Distribution (BSD) license. This license does not prevent proprietary appropriation.

<sup>14</sup> It could be argued that users who do not purchase or transact to use the software would not necessarily be bound to the terms of the license. Legal scholars such as (Lee, 1999) have argued that use and acceptance of the licensing terms may be considered adequate consideration.

434 this means that the GPL only applies to a small per-  
435 cent of users: those who modify and redistribute code.  
436 These users are most likely to have commercial intent.

437 Ninety to ninety-five percent of the people that use  
438 free software have never agreed to the GPL because  
439 they aren't undertaking activities governed by copy-  
440 right law. They are not copying, they are not mod-  
441 ifying, they are not redistributing. They grabbed it  
442 once from a Website, put in on their computer, and  
443 they are just using [it]. They have no obligations  
444 under GPL whatsoever. It's only the small five to  
445 ten percent of people who actually undertake those  
446 activities that are even bound by the license because  
447 they've undertaken things governed by copyright  
448 law (*Informant, Non-Profit Foundation*).

449 The GPL targets a specific audience: those most likely  
450 to withhold contributions to the code base. Software  
451 licensed under the GPL may thus be less attractive to  
452 commercial actors who would like to make proprietary  
453 derivative works. While it has been argued that this  
454 clause inhibits commercial adoption and innovation of  
455 GPL code, it can also be considered a clever way to  
456 prevent behavior that might threaten the sustainability  
457 of freely available code.

458 This safeguard ensures that code from potential con-  
459 tributors, who might otherwise worry that the com-  
460 mons to which they contribute will be decimated, will  
461 be preserved indefinitely for those who have con-  
462 tributed (as well as those who have not). Code that is  
463 appropriated for proprietary purposes could be closed  
464 and made unavailable to the commons. In fact, Lee  
465 (1999) has argued that if free software lacked intel-  
466 lectual property protections, there would be no legal  
467 way to prevent the closing of source code.

468 “Because of (2)(b), each contributor to a GPLd  
469 project is assured that she, and all other users, will  
470 be able to run, modify and redistribute the pro-  
471 gram indefinitely, that source code will always be  
472 available, and that, unlike commercial software,  
473 its longevity cannot be limited by the contingen-  
474 cies of the marketplace or the decisions of future  
475 developers” (Moglen, 1999).

476 Informants using the GPL do not use it to exclude oth-  
477 ers from using their work, but to codify a norm of reci-  
478 procity and temperance or, in other words, to prevent  
479 code from becoming subtractable in the future. Thus,

the problem that the GPL targets is not the inability 480  
to exclude non-contributors (a free rider problem), but 481  
the inability to prevent the proprietary appropriation 482  
of work in the public domain. This tactic would how- 483  
ever, mean little if it went unsanctioned. 484

#### 4.2. Legal and normative sanctions 485

Informants from community managed projects en- 486  
force compliance with their licenses through formal 487  
and informal means. The method of enforcement may 488  
depend upon whether the violation is a commercial or 489  
a community one. A “community violation” or a viola- 490  
tion by a long-standing community member that is 491  
not a part of commercial work may be handled inform- 492  
ally through discussions on project or community 493  
wide mailing lists. A community violation might in- 494  
clude improper use or application of the license, re- 495  
moval of copyright terms, or improper co-mingling of 496  
GPL code with proprietary code. A commercial viola- 497  
tion is more problematic as it is more likely to in- 498  
volve distribution of the offending software. A vendor 499  
selling free software that does not provide the source 500  
code or honor a customer's request for the source code 501  
is a common commercial violation. Reports of source 502  
code violations often comes from customers of such 503  
vendors who post to a community list or report the 504  
infraction to the copyright holder. 505

We had three people writing to us saying, “My com- 506  
pany brought this product from them, because we 507  
need this [...] tool for the work we were doing, 508  
and we discovered that it looks like it is based on 509  
[your software], and darn it they didn't give us the 510  
source code (*Informant, Non-Profit Foundation*). 511

Legally, copyright holders are the only ones with 512  
the right to enforce the licenses associated with their 513  
work (US PTO, 2001). However, informants felt that 514  
the task of monitoring and identifying license viola- 515  
tions was a shared one. The Free Software Foundation 516  
(FSF), the institution founded primarily to enforce the 517  
GNU GPL, encourages those who suspect license in- 518  
fringement to bring it to the attention of those with 519  
the rights to formally take action. “. . . [R]eport it (the 520  
license infringement). First, check the facts as best 521  
you can. Then tell the publisher or copyright holder 522  
of the specific GPL-covered program.” (Free Software 523  
Foundation, 2001). The FSF will pursue violations of 524

**Box 1.** Example of a reported GPL violation  
GPL violation?

By anonymous reader on 14 January 2002 12:13  
(#5500).

- <http://www.ozone.com> does not mention which Linux kernel version is used and definitely does not supply kernel source code.
  - They have a flash demo of the product where the autoupdate section clearly shows tools like “xinetd” “alsa-driver” “readline” and “setup”. One or more these packages are bound to be GPL'ed (alsa-driver and readline). “Readline” may well be a product of a GNU project.
  - Since no source code is supplied for so many GPL'ed software tools, specifically kernel and other GNU software tools, while their binaries are being distributed for money, I think this may be a possible case of GPL violation.

(Note: from <http://newsforge.com/newsforge/02/01/10/1922249.shtml?tid=23>.)

525 work to which they hold copyrights and offer assistance to other copyright holders as requested. One informant reported receiving approximately two to five violation reports a week, although only about one every 2 weeks was found to be a valid violation. Box 1 presents an example of a report of a GPL violation from a community member posted to a public open source community website.

533 Community managed projects also use formal legal mechanisms to alert violators of a licensed work that are much like those used by firms. Legal counsel may be obtained to draft a “cease and desist” style letter to enforce compliance with the license.

538 If you break the license, then you get a letter from the lawyer. It's a standard copyright violation. If you break the license, you have violated the copyright, just as if you had stolen music from Napster or illegal pirated DVDs (*Volunteer Contributor, GUI Desktop Project*).

544 Formal approaches are however, designed to encourage compliance, not to seek damages. To comply with the license, a violator might have to provide their

547 source code or, in a more complex situation, remove GPL code from a proprietary related code base. A violator with co-mingled code could of course resolve the violation by re-licensing the offending proprietary code under the GPL. 551

552 We never threatened damages. We certainly said, If you don't work with us we are going to have to seek damages [...]. What we want you to do is not onerous. We want you to comply with the license, which either means stop what you are doing in violation, or bring your product into compliance, which is usually the thing that they pick. Once you bring the product into compliance we ask that you appoint a GPL compliance officer within your organization who is at a high enough level that when we find a GPL problem in the future we can call them up and have a line of communication (*Informant, Non-Profit Organization*). 564

565 Those informants who discussed enforcement emphasized that compliance was the primary remedy sought, but held out a further power articulated in the GPL that grants copyright holders the ability to withhold the freedoms granted in the license upon notice of a violation. Section 4 of the GPL states that “any attempt otherwise to copy, modify, sublicense or distribute the Program is void, and will automatically terminate your rights under this License.”<sup>15</sup> This clause provides some enforcement capability in that copyright holders can ask violators to stop distribution of software that is not in compliance until the violation is resolved. Once resolved, it is up to the copyright holder to restore the violator's rights. 578

579 As of this writing, formal legal enforcement actions have not resulted in any known court cases that would require defending the GPL.<sup>16</sup> Companies that have been notified of a violation may take time to comply, but informants reported that most engage in good faith efforts to come into compliance. For example one company that violated the GPL, but has 585

<sup>15</sup> <http://www.gnu.org/licenses/gpl.txt>.

<sup>16</sup> From a legal perspective, the GPL has not been tested in a court of law, although legal analysts (e.g. Lee, 1999; McGowan, 2001) have argued that it would be defensible. A legal counsel to the Free Software Foundation has said that if tried, the GPL would be treated like any other copyright violation and draw on precedents from copyright case law.

586 since come into compliance, announced to customers  
587 on their website that:

588 We have temporally closed the services due to  
589 the fact that our products were against [the] GPL,  
590 however the problem has been settled, with all  
591 related parties' support. We deeply regret any in-  
592 convenience you have experienced, and hope that  
593 you will enjoy our services again (Epson Kowa  
594 Corporation).<sup>17</sup>

595 Informants from Fortune 500 firms reported that  
596 their firms were well aware of the need to comply  
597 with the licensing terms and norms of the community  
598 and that they did make changes when violations were  
599 detected.

600 Informal enforcement of license terms draws upon  
601 the normative roots of the license and occurs primar-  
602 ily through on-line public forums. The GPL codifies  
603 a strong norm of reciprocity that has long been an  
604 important part of the programming culture (Williams,  
605 2002; Levy, 1994). Raymond (1999) has described  
606 this culture as a gift culture. However, this conception  
607 connotes the idea of transactions from one to another.  
608 The norm of reciprocity may be best understood as a  
609 subtle pressure to contribute to a collectively managed  
610 commons.

611 The idea of the GPL is that if you want to include  
612 our code in your program, your program must also  
613 be free software. *It is supposed to put pressure on*  
614 *you* to release your program in a way that makes it  
615 part of our community (Founder, GNU Project and  
616 Free Software Foundation).

617 There is no limit on what one can take from the com-  
618 mons, but one is expected at some time, to contribute  
619 back to the commons to the best of one's abilities.

620 Legal scholars (McGowan, 2001; Lessig, 1999a,b,  
621 c,d,e; Lee, 1999; Gomulkiewicz, 1999; Moglen, 1999)  
622 have emphasized that the GPL, while grounded in  
623 copyright law, cements the values of the community  
624 and can help counteract commercial pressures that  
625 might violate community norms. An attorney who ad-  
626 vises both corporate and community clients on the  
627 GPL stated that:

I don't want to give the legal system too much 628  
credit. It [the GPL] also works because there is a 629  
whole community ready to accept it. There is a 630  
norm of good behavior (*Independent Private Legal* 631  
*Counsel*). 632

In the eyes of both legal scholars and informants, the 633  
GPL's strength stems not necessarily from its legality, 634  
but from the public collective opinion of community 635  
members. Informants also stressed that the primary 636  
vehicle by which they could enforce their license terms 637  
was by identifying and critiquing violations on on-line 638  
mailing lists and bulletin boards. 639

So far no one has had to litigate [...]. And also 640  
a very big thing that I have used, is they fight it 641  
out in the court of public opinion (*Former Volun-* 642  
*teer, Project Founder, Sponsored Contributor, De-* 643  
*bian Linux Distribution Project*). 644

The court of public opinion is conducted on In- 645  
ternet based on-line bulletin boards or mailing lists. 646  
All six projects maintain a number of mailing lists to 647  
which contributors, users and other interested parties 648  
post to on a frequent basis. Almost all informants also 649  
participated in non-project based mailing lists<sup>18</sup> that 650  
discussed issues relating to events in the larger open 651  
source and free software communities. 652

There are a couple of theoretical reasons why dis- 653  
cussion in on-line discussion forums might have a 654  
strong normative effect on community and corporate 655  
contributors. First, postings to project mailing lists are 656  
public and not anonymous. Communications between 657  
any two members are available to all members. Prior 658  
research (Fernandez and McAdam, 1988; McAdam 659  
and Paulsen, 1993; Gould, 1993; McAdam, 1996) 660  
has shown that individuals contributing to a collec- 661  
tive good do so interdependently and are affected by 662  
the nature and structure of their network relations. 663  
The social presence of others can motivate further 664  
contributions, despite free rider concerns (Guttman, 665  
1987; Gould, 1993). Norms of fairness and efficacy 666  
can inspire individuals to contribute when other in- 667  
dividuals in their network contribute (Gould, 1993). 668  
From an economic perspective, it is information, and 669  
not norms, that can lead to a positive matching effect 670

<sup>17</sup> Epson Kowa Corporation, located at: [http://www.epkowa.co.jp/english/linux\\_e/linux.html](http://www.epkowa.co.jp/english/linux_e/linux.html).

<sup>18</sup> Examples of these forums include: Slashdot, freshmeat, kuro5in, Linuxworld, Linuxtoday, Linux journal.

(Guttman, 1987). If people have reliable information on the contributions of others, than they may be more likely to “match” those contributions and contribute as well. Both sociological and economic explanations suggest that any mechanism that enhances the visibility of both norms and information might have a positive mutually reinforcing effect on encouraging individuals to contribute to collective goods.

Informants thought that on-line public forums were an effective and powerful tool to ensure that others who adopted their work did so without violating community norms and licenses. Formal sanctioning was most evident on the GNU project, which is not surprising given the fact that the GPL was initiated for this project. As Table 3 indicates, evidence of informal sanctioning was found on all projects. There is suggestive evidence that firms using open source and free software understood and respected both formal and informal sanctioning tactics.

#### 4.3. Incorporate

Five out of the six projects<sup>19</sup> created a legal entity to hold their intellectual property and protect volunteer contributors from individual liability by incorporating and forming a non-profit foundation.<sup>20</sup> How does incorporation protect a community managed project? A community managed project that is instantiated through mailing lists and web pages does not have any legal rights. It cannot sign contracts or hold property. Informants assumed that intellectual property rights could be better defended with a legal entity supporting their projects. They wanted to establish an institution so that projects could live beyond the efforts of their founders, but most importantly, they wanted to gain the same protections and privileges afforded to corporations. Incorporation allows projects to protect volunteer contributors from individual liability, enter into agreements collectively, and protect their code, trademarks, licenses, and brand. Forming a non-profit was a means to an end, a means to allow project contributors to maintain control over their

organization in a manner that could be recognized by other commercial and legal entities (Hansmann, 1996).

The special tax exemptions that the United States government grants to non-profit organizations rest upon the assumption that non-profits behave differently from firms (Powell and Clemens, 1998; Weisbrod, 1998). DiMaggio and Anheier (1990) suggest that non-profit organizations signal trust-worthiness, primarily because their non-distribution constraint prescribes distributing net income (Hansmann, 1980) and because they typically pursue goals that differ from firms. Non-profit organizations may be more appealing when certain goods are seen as inappropriate for market exchange or requiring special protection from corruption by the profit motive (DiMaggio and Anheier, 1990, p. 144). Hansmann also predicts that such associative organizations are more likely to appear where consumer control is low cost (Hansmann, 1996). The creation of a non-profit foundation to hold a community managed project's assets would seem to indicate that informants wanted to protect their work in ways that were different from market exchange while garnering the rights associated with incorporation.

#### 4.4. Transfer individual property rights to a foundation

Intellectual property rights are better defined and more defensible when owned by a single legal entity. For example having a single and central copyright holder is easier than negotiating the swift cooperation of hundreds of contributors holding individual copyrights, particularly if electronic signatures are not legally recognized. In addition, informants in leadership positions on several projects were advised by their legal counsel that assigning copyrights to a non-profit organization would help to reinforce institutional as opposed to individual liability.<sup>21</sup>

The reasons informants offered for wanting to transfer copyright assignment to a legal entity were to se-

<sup>19</sup> The Linux kernel project remains unincorporated and also used the least number of legal tactics of the six projects studied.

<sup>20</sup> How these non-profit foundations are designed and governed is discussed in O'Mahony (2002).

<sup>21</sup> Independent legal counsels have advised some community managed projects that the liability protection extended to individuals through incorporation may not protect individuals from potential liability associated with their code if individual copyrights are not assigned to the corporation.

752 cure legal protections for their code, formally limit individual liability and improve their ability to pursue enforcement actions.

755 One of the original goals of the [foundation] in those days was to be the legal shell for the GNU project. That included collecting these copyright assignments. Now the reason that we did that was because of the issues related to enforcement (*Informant, Free Software Foundation*).

761 Yet, of the seven tactics identified, this tactic was the least popular among the projects and the most controversial. Contributors on four of the six projects transferred individual copyrights to non-profit foundations in order to better secure and defend the project's rights but no project required such transfer as a condition of contribution.

768 Only two of the six projects explicitly ask individuals to assign their copyrights to the foundation. The GNU and Apache projects were the most active of the six projects in encouraging contributors to assign their copyrights to a non-profit entity, but even they were reluctant to make this a condition of contribution.

774 We took the stance that you should have an organization that owns the code, so the [foundation] does own the copyright on all the code. And we are not as good about this as we should be, but we do try to ask the core developers to sign over copyright assignment to us (*A Founder and Project Leader, Apache Webserver Project*).

781 Debian does not encourage software authors to assign copyrights to their foundation, but states that their foundation is willing to hold them in some circumstances. The Linux kernel project also does not encourage authors to assign copyrights.

786 [Copyright] Transfer? No, I think that is amoral. Plus, I hate paperwork. So everybody keeps their own copyright. It makes people comfortable about the fact that there is no single copyright holder. So even if I turn over and I rip off the mask, [he is joking] I could not change the way it is licensed. Well in practice, there are not that many people who have even bothered to put their own copyrights on code. There are a couple hundred or something, so to actually change the license would be practically impossible, which is what makes people feel com-

797 comfortable with it (*Founder and Project Leader, Linux kernel project*). 798

799 In explaining his lack of interest in copyright assignment, this informant also articulates a source of conflict that stems from the use of legal mechanisms to control code by those trying to avoid restrictions over their code. 800 801 802 803

804 In the hacker<sup>22</sup> culture, individual merit, autonomy, and problem solving ability are paramount (*Williams, 2002; Raymond, 1999; Levy, 1994*). Hackers believe that “information sharing is a powerful positive good, and that it is an ethical duty to share their expertise by writing free software and facilitating access to information and computer in resources wherever possible” (*Raymond, 1999, p. 236*). While all of the legal tactics identified could be considered to be antithetical to the hacker ethic to some degree, the strain between these conflicting worlds was most apparent in copyright assignment practices. One informant's comments when discussing who owns the Apache code reflect the dichotomy that exists between a culture that embraces what might be considered a libertarian ethic with one that relies upon legal controls. 805 806 807 808 809 810 811 812 813 814 815 816 817 818 819

820 Legally, the foundation owns the code. However, having said that, the people who write the code own the code [...]. If you have ever gotten a piece of code into Apache, you own that code, its yours and you should feel proud of it (*Sponsored Contributor, Apache Project*). 821 822 823 824 825

826 This informant first provides a legal answer, and then modifies that answer to provide an answer that maintains consistency with norms of the hacker culture. 827 828

829 One reason why copyright assignment may ignite such disparate approaches and practices is because it infringes on the norms of the hacker culture more so than the other tactics discussed. When an individual assigns their copyright to the foundation, ownership is transferred to a non-profit entity managed by project leaders. This act may constitute a greater compromise of the hacker ethic than some were willing to make, as evidenced by the informant who felt that requiring copyright assignment was amoral. On a different 830 831 832 833 834 835 836 837 838

<sup>22</sup> A hacker is defined as “a person who enjoys exploring the details of programmable systems and how to stretch their capabilities ... one who programs enthusiastically (even obsessively) or who enjoys programming” (*Raymond, 1999, pp. 233–234*).

839 project, when other project members perceived an  
840 individual as having too much ownership over the  
841 code, the conditions of collective ownership were  
842 reinforced.

843 And you know this was kind of the shock. He says  
844 “this isn’t your code, this is our code. If you think it  
845 is [your code], I will take your code out of this tree,  
846 and put this [other] code back in [ . . . ].” And some-  
847 body else basically said to him, “you cannot take his  
848 code out because it isn’t your code any more than  
849 it isn’t his code.” It’s one of those things, checks  
850 and balances (*Sponsored Contributor; Apache*  
851 *Project*).

852 The idea of collective ownership was unfamiliar to  
853 all three parties of the on-line conversation recaptured  
854 by the informant above. This discussion demonstrates  
855 how individuals might keep each other’s interpretation  
856 of what collective ownership could mean in practice  
857 in check.

858 An informant from one of the projects that was vig-  
859 ilant about copyright assignment best articulated the  
860 tension embedded in programmers’ use of legal mech-  
861 anisms to preserve a culture that strives to be free of  
862 them.

863 So, we are in this odd situation as people who  
864 want as few legal restrictions as possible on soft-  
865 ware, but we are pragmatic enough to realize that  
866 without some legal protection we would loose the  
867 community we built. [ . . . ] We didn’t want a world  
868 with lots and lot and lots of licenses. That wasn’t  
869 our goal. Our goal was to build freedom in the  
870 system we had, this flawed system where for some  
871 reason somewhere in the 1960s or 70s there was  
872 a decision made that copyright law would cover  
873 software. We have to work within the decision that  
874 exists and it is the default belief in the industrial-  
875 ized world at least. So, we have to build legal  
876 systems within copyright laws to defend freedom  
877 (*Informant, Non-Profit Foundation*).

878 Informants from projects that pursued active copy-  
879 right assignment policies (the GNU and Apache  
880 projects) were also more likely to worry about the  
881 existence of work-for-hire agreements among their  
882 contributors. Firms that hire programmers typically  
883 ask them to sign an “Assignment of Pre-Employment  
884 Works” or a “Confidentiality and Invention Assign-

ment Agreement” that transfers ownership of all works  
885 created by the employee on company premises and  
886 using company resources to the company. The Free  
887 Software Foundation asks contributing code authors  
888 to not only transfer their copyright but to demonstrate  
889 that they are free from work-for-hire agreements and  
890 clearly own the code they are contributing (Moglen,  
891 2001). Several informants reported revising their  
892 agreements with their employers so that they could  
893 contribute code to community managed projects, but  
894 it was unclear if and how different projects coun-  
895 selled their contributors on how to modify these  
896 agreements. 897

#### 4.5. Trademark brands and logos designed to represent their work 898 899

All six projects have developed distinct brands or lo-  
900 gos and have filed trademarks<sup>23</sup> with the US Patent and  
901 Trademark Office (US PTO) to protect their brands. 902

We could still try to claim trademark while getting  
903 the foundation incorporated and put it on the web  
904 site (*Board Meeting, 28 November 2000, GNOME*  
905 *GUI Desktop Project*). 906

A primary motivation for filing a trademark was  
907 to ensure that the project would be uniquely distin-  
908 guished and to prevent others from confusing a project  
909 with related work. Some informants recognized that  
910 some level of active defense of their mark was needed  
911 in order to prevent their project name or symbol from  
912 ending up in the public domain. Thus, transferring  
913 trademark rights to a foundation was an attractive op-  
914 tion for most projects. 915

#### 4.6. Assign trademarks to the foundation 916

Five out of the six projects have assigned trade-  
917 mark rights to a non-profit entity or foundation cre-  
918 ated to support the project. For example the Apache  
919 webserver project’s trademark agreement states  
920 that:

<sup>23</sup> A trademark is a word, name, symbol or device that is used in  
trade to indicate the source of the goods and to distinguish them  
from the goods of others (US PTO, 2001).

921 WHEREAS, the Foundation desires to acquire all  
922 right, title and interest, Member has to the Trade-  
923 marks . . . Member by these presents does sell, as-  
924 sign and transfer unto the Foundation, and its suc-  
925 cessors and assigns, Member's entire right, title,  
926 and interest (*Apache Trademark Assignment Form,*  
927 *Board Meeting Minutes, 27 April 1999*).

928 Project members collectively manage the trade-  
929 mark, although the specific governance structures  
930 vary by project. For example while members of the  
931 Apache Software Foundation manage the trademark  
932 for the Apache project, project members, as opposed  
933 to foundation board members, are the ones who man-  
934 age the mark for the Debian project. The Linux kernel  
935 project was the only project that has a trademark  
936 held by an individual. Day-to-day management of  
937 the trademark is delegated to a law firm and trusted  
938 advisor.

939 Interviewer: Why is it [the Linux trademark] as-  
940 signed to a person versus Linux International [a  
941 non-profit foundation]?

942 Informant: We were afraid of corporations taking  
943 over who might do nasty things. [The project leader]  
944 was the only one that was trusted (*Informant, Linux*  
945 *International*).

946 This may be because the Linux kernel project is not  
947 directly supported by a non-profit foundation and has  
948 resisted efforts to adopt that type of structure. Without  
949 a legal entity, the management of intellectual property  
950 rights remains at an individual level.

#### 951 4.7. *Actively protect brand*

952 Evidence of activity to protect the brand and collec-  
953 tive reputation of the project was found across all six  
954 projects. Why would community managed projects  
955 worry about protecting their brand? Project contrib-  
956 utors felt that protecting their brand was especially  
957 important when their work was repackaged and dis-  
958 tributed by firms. While it is legally possible for firms  
959 to effectively rebrand the work produced by particu-  
960 lar projects with minimal to no recognition, project  
961 contributors preferred to establish what marketing  
962 researchers might call co-branded relationships with  
963 firms. When a product or service is co-branded, two

964 contributing brands to the product or service are rec- 964  
965 ognized (Kotler, 2002).<sup>24</sup> Co-branding was attractive 965  
966 to project contributors for several reasons. 966

967 First, contributors wanted to ensure that they re- 967  
968 ceived appropriate credit and recognition for their 968  
969 work. Firms selling products and services that in- 969  
970 corporate community managed software may be re- 970  
971 quired to incorporate appropriate acknowledgement 971  
972 of the project's contributions and, in some cases, the 972  
973 project's copyrights trademarks. 973

974 The only place you found in [firm name]'s [prod- 974  
975 uct], that said the word Debian was on the first page 975  
976 of their manual, we would like to thank Debian for 976  
977 their help. If you did not know what Debian was 977  
978 . . . Is that a group? A people? A piece of software? 978  
979 (with disgust) That was all they gave us. There was 979  
980 never a Debian logo, there was never a Debian any- 980  
981 thing (*Sponsored Contributor and former Volunteer*  
982 *Contributor, Debian Linux Distribution Project*). 982

983 This informant is concerned not about recognition 983  
984 for himself, but for the project. In a commercial con- 984  
985 text, what mattered to informants was ensuring that 985  
986 the project, as a whole, received the appropriate recog- 986  
987 nition. The other insight that is apparent from this 987  
988 quote is that a firm's minimal acknowledgement of 988  
989 a project's efforts was a necessary, but not sufficient, 989  
990 step toward maintaining collegial firm and community 990  
991 relations. 991

992 The second reason was more pragmatic. Projects 992  
993 wanted to be recognized, but they did not want their 993  
994 work to be confused with that of the firms distributing 994  
995 their work. Project members wanted to preserve the 995  
996 project's reputation, and did not want problems that 996  
997 might be related to a firm's product to be incorrectly 997  
998 associated with their code. 998

999 They [a firm] made CDs that would not install for 999  
1000 some reason. People would write to Debian and it 1000  
1001 would not be [our code]. So Debian started making 1001  
1002 official CDs. And I attached it to the Debian trade- 1002  
1003 mark, which thank goodness is a real trademark, 1003  
1004 and said you may call your product official Debian 1004

<sup>24</sup> While co-branding has become popular in recent years, few component manufacturers are successful in establishing an identity separate from the product to which they contribute. Well known successful examples who have proved otherwise include Intel, Nutrasweet and GORE-TEX® (Kotler, 2002, pp. 434–435).

1005 if it is made from our CD masters and if you in-  
 1006 clude the source CD and the binary CD” (*Former*  
 1007 *Volunteer Contributor and Project Leader, Debian*  
 1008 *Linux Distribution Project*).

1009 As this informant explains, by creating a CD master,  
 1010 the Debian project retains some degree of control over  
 1011 the representation of their work and, in doing so, can  
 1012 protect their collective reputation.

1013 While several theorists have emphasized that indi-  
 1014 vidual reputation may be a critical motivator to in-  
 1015 spire individuals to contribute to open source projects  
 1016 (Raymond, 1999; Weber, 2000; Lerner and Tirole,  
 1017 2002b), few have recognized the value of the collec-  
 1018 tive reputation. The use and defense of brands and  
 1019 trademarks by community managed projects suggests  
 1020 two things: It suggests that the collective reputation of  
 1021 the group may matter as much, if not more, to volun-  
 1022 teer contributors than individual reputation; secondly,  
 1023 it suggests that open source projects value and protect  
 1024 their identity as a community of developers as much  
 1025 as they do the product of their collective efforts.

1026 Three of the six projects used all seven tactics,  
 1027 and all of the projects used at least four tactics. All  
 1028 projects used legal and normative sanctions, created a  
 1029 logo, filed for a trademark, and actively protected their  
 1030 brand. Projects varied most in their willingness to as-  
 1031 sign intellectual property rights to a non-profit foun-  
 1032 dation. What is unique about the seven legal tactics  
 1033 examined in this study is that the rights retained by the  
 1034 licensors (individuals and, in some cases, community  
 1035 managed projects) are not the rights for which these  
 1036 tools are traditionally designed, but those most closely  
 1037 aligned with the licensor’s values. These values are  
 1038 less concerned with restricting access to the licensor’s  
 1039 work and more concerned with preserving access. To  
 1040 do so, the rights and privileges associated with these  
 1041 intellectual property mechanisms are unbundled and  
 1042 redistributed. For example the GPL grants the rights  
 1043 to use, modify, distribute, and perform to the licensee.  
 1044 This would seem to redistribute the balance of power  
 1045 from the licensor to the licensee. However, these rights  
 1046 are not unbound. Licensees are not allowed to restrict  
 1047 access to the code or impinge on the freedoms of oth-  
 1048 ers to make use of the code. Licensees are granted  
 1049 the right to sell the community’s work for a profit,  
 1050 but they must do so in a way that distinguishes the  
 1051 community’s work and acknowledges their contribu-

tion to a commercial product. Thus, a subtle rebal- 1052  
 ancing of rights is achieved, by transferring power to 1053  
 the licensee, but by making this power conditional on 1054  
 cooperation with community norms. 1055

## 5. Discussion 1056

This examination was motivated by the discovery 1057  
 of discrepancies between the way informants conceive 1058  
 of and treat the product of their collective efforts, and 1059  
 the way observers discuss and think about open source 1060  
 software. The projects in this study freely provide their 1061  
 source code to the public. Individuals and firms can 1062  
 download it from the Internet and use it to further 1063  
 their personal or commercial goals. However, these 1064  
 projects also use legal and normative tactics to pro- 1065  
 tect their source code from proprietary appropriation 1066  
 and to protect their collective identity and reputation. 1067  
 This research shows that contributors to community 1068  
 managed projects have interests and rights over their 1069  
 work, and that they are interested in protecting their 1070  
 intellectual property. The assumption that open source 1071  
 contributors give their work away must be modified 1072  
 in order to account for the ways in which community 1073  
 managed projects protect their work. 1074

Moglen (1999), among others (Tuomi, 2000), have 1075  
 argued that Section (2)(b) of the GNU GPL creates a 1076  
 commons “to which anyone may add but from which 1077  
 no one may subtract.” Without the legal tactics identi- 1078  
 fied in this study, open source and free software might 1079  
 be in danger of becoming a subtractable good. While 1080  
 the availability of open source software will not di- 1081  
 minish with greater use, those who do not comply with 1082  
 the norms of the community could diminish its future 1083  
 value and its availability to others. 1084

Interviewer: How critical is the GPL to the moral 1085  
 and ethical foundation of . . . ? 1086

Informant: Well the GPL is what makes free soft- 1087  
 ware survive in a copyrighted world (*Open source* 1088  
*firm founder and contributor to several projects*). 1089

There is a threat that requires a defense. To stay 1090  
 open and remain publicly available, open source and 1091  
 free software requires protections from risks inherent 1092  
 with work in the public domain. While open source 1093  
 and free software initially resembles a public good, it 1094

1095 also faces some of the risks faced by common pool  
1096 resources.

1097 How do the mechanisms used by community man-  
1098 aged projects compare to those used in prior studies  
1099 of common pool resource problems? Mechanisms to  
1100 manage common pool resources usually restrict ac-  
1101 cess to the resource or create incentives to use the re-  
1102 source with more temperance (Ostrom, 1999). Groups  
1103 that are better able to identify each other are more  
1104 likely than groups of strangers to draw on trust, reci-  
1105 procity, and reputation to develop norms that limit use  
1106 (Ostrom et al., 1999, p. 279; Ostrom, 1999). Groups  
1107 that are better able to monitor and coordinate activities  
1108 are more likely to develop mechanisms that can help  
1109 them sustainably manage their resources. In general,  
1110 actors are more likely to develop solutions to com-  
1111 mon resource pool problems, if they have “some au-  
1112 tonomy to make and enforce their own rules and they  
1113 highly value the future sustainability of the resource”  
1114 (Ostrom et al., 1999, p. 280).

1115 Contributors to the community managed projects in  
1116 this study envisioned a long future working with the  
1117 software to which they contributed. For example the  
1118 Debian Linux Distribution project has been in opera-  
1119 tion for over 9 years, has withstood six different lead-  
1120 ers, and continues to grow with over 1000 registered  
1121 contributing members. It is also clear from the tactics  
1122 used, that contributors highly value the results of their  
1123 efforts. Informants spoke of their contributions as in-  
1124 vestments in their future tools: they are creating code  
1125 that they will never have to pay someone to use again.  
1126 Because of the rights community managed projects ex-  
1127 ercise, it can be said that contributors pool their efforts  
1128 to create collectively owned and managed resources.  
1129 Furthermore, because the context of community is pri-  
1130 marily on-line public forums, contributors' efforts are  
1131 highly visible, which facilitates the communication of  
1132 norms and information that enables monitoring and  
1133 co-ordination. These factors suggest that this is an en-  
1134 vironment that is conducive to developing mechanisms  
1135 to help manage common pool resource problems.

1136 These principles also point to some fundamental  
1137 differences between common pool resources and open  
1138 source software. Unlike common pool resources,  
1139 open source software is always publicly available.  
1140 Resources do not need to be redistributed or limited  
1141 on any scheduled basis. What this analysis has es-  
1142 tablished is that open source and free software is not

quite a public good and not quite a common pool 1143  
resource, at least, in the way these types of goods 1144  
have been previously defined. The problem with clas- 1145  
sifying open source software as a pure public good 1146  
is that this conception glosses over some of the more 1147  
interesting features of community managed software 1148  
projects. In neglecting to critically examine how old 1149  
terms are applied to new phenomena, we risk misun- 1150  
derstanding the very mechanisms that may support 1151  
its resiliency. Before despairing the introduction of 1152  
murkier levels of complexity, consider Von Hippel 1153  
and von Krogh's charge that “efforts to offer clean 1154  
and simple models [of private and public goods] for 1155  
research have excluded from consideration a very rich 1156  
and fertile middle ground where incentives for pri- 1157  
vate investment and collective action can coexist and 1158  
a private-collective innovation model can flourish” 1159  
(2002, p. 11). 1160

1161 In the case of open source and free software, this  
1162 rich and fertile middle ground can be further explored  
1163 by rethinking how the law is used to manage rights  
1164 to digital intellectual property. Von Hippel and von  
1165 Krogh acknowledge a long understood tension in le-  
1166 gal theory: the rights of innovators must be balanced  
1167 with the rights of the public. Copyright protections are  
1168 granted to allow investors to earn a return on their in-  
1169 vestment while also providing an incentive for innova-  
1170 tors to disclose their works so that the public can ben-  
1171 efit from them. This study suggests that the efficacy of  
1172 copyright law in balancing public and private interests  
1173 may be called into question when applications of the  
1174 law are inverted in order to achieve its founding intent.  
1175 An alternative interpretation is that, in an era of dig-  
1176 ital intellectual property, copyright law has untapped  
1177 elasticity in facilitating new possibilities in unbundling  
1178 and re-bundling rights and re-balancing public and pri-  
1179 vate interests. If this is the case, it is paradoxical that  
1180 explorations into the elasticity of copyright law have  
1181 been most thoroughly explored by those least inter-  
1182 ested in restricting access to protected works.

1183 Digital intellectual property and the creative appli-  
1184 cation of traditional legal mechanisms enable commu-  
1185 nity managed projects to decouple the ability to govern  
1186 their work from its circulation and possession. This  
1187 redistribution of rights has been difficult to concep-  
1188 tualize, as these rights are directed towards goals to  
1189 which the commercial sector is unaccustomed. How-  
1190 ever, these mechanisms should not be under valued

1191 because of their ideological underpinnings. If we leave  
 1192 the world of political science and turn to computer sci-  
 1193 ence, the tactics used by community managed projects  
 1194 form what Stefik (1997a) might call a trusted system.  
 1195 A trusted system has rules governing the terms, con-  
 1196 ditions and fees for using digital works. In a trusted  
 1197 system, property rights are respected, but transport  
 1198 rights (rights to copy), rendering rights (rights for play-  
 1199 ing and printing) and derivative works rights (extract-  
 1200 ing, editing, and embedding protected works in other  
 1201 works) can be disaggregated and managed under dif-  
 1202 ferent terms (Stefik, 1997b). Stefik argues that while  
 1203 publishers often think that digital technology automat-  
 1204 ically transfers more power to users, trusted systems  
 1205 can also be used to shift the balance and put more  
 1206 power in the hands of the publishers.<sup>25</sup> Stefik thinks  
 1207 that one reason why this has not happened is because  
 1208 the social framework to support trusted systems is un-  
 1209 derdeveloped (Stefik, 1997a). While Stefik argues that  
 1210 technology is what can change the balance between  
 1211 publishers and users, it is perhaps ironic that hackers,  
 1212 who are among the most sophisticated users of tech-  
 1213 nology, are using a combination of legal and norma-  
 1214 tive sanctions to do just that.

1215 The term digital rights management has been used  
 1216 to reinforce rights that restrict use of protected works.  
 1217 However, with a broader definition of such a term, it  
 1218 could also be argued that this is precisely what the  
 1219 community managed software projects in this study  
 1220 do: manage, exercise and defend rights to digital intel-  
 1221 lectual property. The ability to manage rights to digital  
 1222 works must not become conflated with a specific aim,  
 1223 for this would narrow the types of possible outcomes,  
 1224 just when we are presented with unparalleled flexibil-  
 1225 ity. This research suggests that this type of flexibil-  
 1226 ity may lend itself to solving some traditional collec-  
 1227 tive action problems and that further research in this  
 1228 area could contribute to new insights in the design of  
 1229 new social arrangements to manage digital intellectual  
 1230 property.

1231 Future research must also devote greater attention  
 1232 to the mechanisms that community managed projects  
 1233 use to govern themselves and manage their work, espe-  
 1234 cially when it is distributed in commercial markets or  
 1235 becomes the basis for de facto standards. This is partic-

<sup>25</sup> While Stefik is referring to firms, this could also apply to the case at hand.

ularly important for policy makers because as Lessig  
 (1999c) suggests, the ownership of software is likely  
 to effect regulatory actors stance toward it. When the  
 ownership of code is firmly established, governmen-  
 tal authority is more easily assured. When the own-  
 ership of code is not as easily established, then too,  
 the ability of government to regulate it will also be  
 less clear (Lessig, 1999c). The degree to which com-  
 munity managed projects continue to evolve in their  
 governance, and the management of their collective  
 resources, may thus affect how governments conceive  
 of and treat their work.
